# Sensor Definition

**Sensor** is a device that detects events or changes in the environment, and transform signals from different energy domains to the electrical domain then provides a corresponding output

# Sensor Outputs

*International Frequency Sensor Association (IFSA), Study, 2016*

# Analog & Quasi-Digital Sensors

**Analog sensor** - sensor based on the usage of an amplitude modulation of electromagnetic processes

**Quasi-digital sensors** are discrete frequency-time domain sensors with frequency, period, duty-cycle, time interval, pulse number or phase shift output

Quasi-digital sensors combine a simplicity and universality that is inherent to analog devices and accuracy and noise immunity, proper to sensors with digital output

# Digital Accelerometer

Toshihiro Itoh, Takeshi Kobayashi, Hironao Okada, A Digital Output Piezoelectric Accelerometer for Ultra-low Power Wireless Sensor Node, in *Proceedings of IEEE Sensors 2008*, 26-29 October 2008, Lecce, Italy, pp.542-545.

# Digital Sensors

- Number of physical phenomenon, on the basis of which direct conversion sensors with digital outputs can be designed, is essentially limited
- Angular-position encoders and cantilever-based accelerometers – examples of digital sensors of direct conversion
- There are not any nature phenomenon with discrete performances changing under pressure, temperature, etc.

# Technological Limitations

- Below the 100 nm technology processes the design of analog and mixed-signal circuits becomes essentially more difficult
- Long development time, risk, cost, low yield rate and the need for very high volumes
- The limitation is not only an increased design effort but also a growing power consumption
- However, digital circuits becomes faster, smaller, and less power hungry

# Quasi-Digital Sensors Types

*International Frequency Sensor Association (IFSA), Study, 2015*

# The First Quasi-Digital Sensors

- **1930** - string distant thermometer  
(Pat. No.61727, USSR, Davydenkov N., Yakutovich M.)
- **1931** - string distant tensometer  
(Pat. No. 21525, USSR, Golovachov D., Davydenkov N., Yakutovich M.)
- **1941** - ADC for the narrow time intervals  
(Pat. No. 68785, USSR, Filipov V.N. and Negnevitskiy S.B.)

# Informative Parameters

- Duty-cycle:  $D.C. = t_p/T_x$
- Duty-off factor:  $1/D.C. = T_x/t_p$
- PWM signal:  $t_s/t_p$  ratio at  $T_x = \text{constant}$

# Period-Modulated Output

# Voltage Output

(a)

$$V_1 < V_2$$

(b)

# Frequency Output

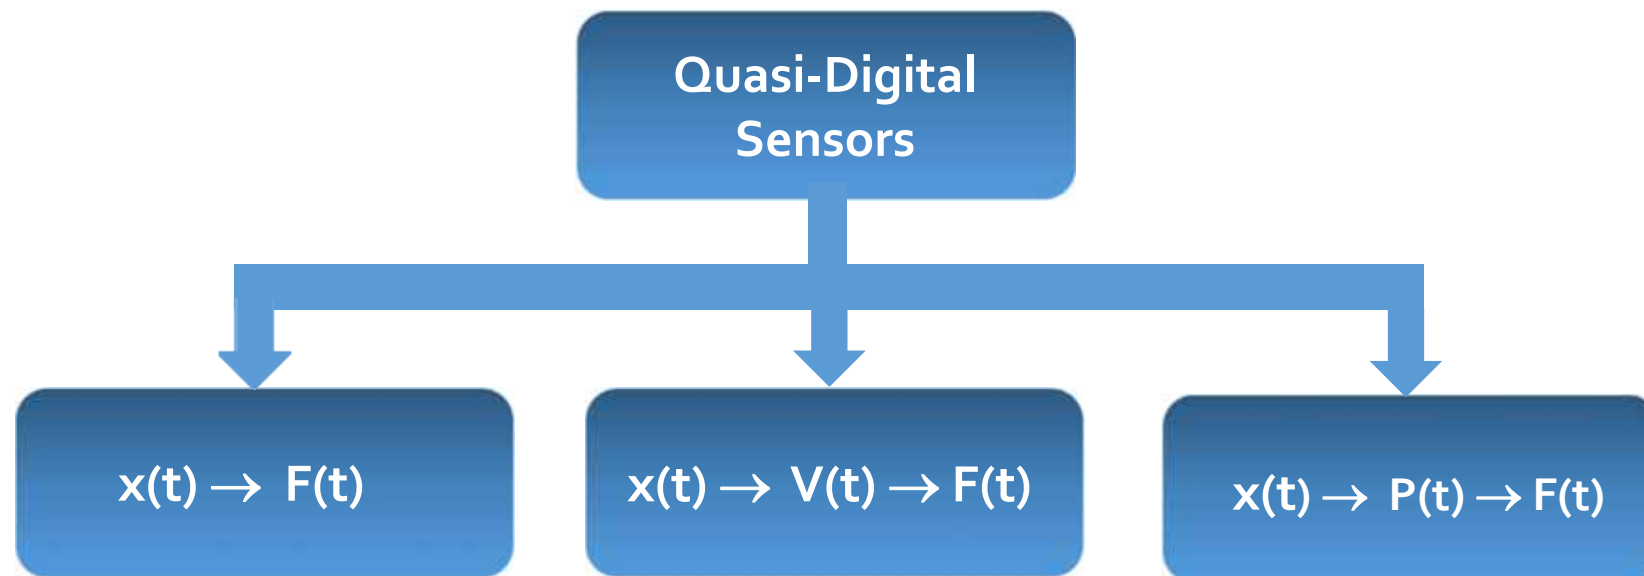

(a)

(b)

$$T_{x1} > T_{x2}, f_{x1} < f_{x2}$$

# Quasi-Digital Sensors Classification

$x(t)$ —measurand;  $F(t)$ —frequency;  $V(t)$ —voltage, proportional to the measurand;  $P(t)$ —parameter

# $x(t) \rightarrow F(t)$ Conversion

- Sensors themselves generate a frequency output
- Electronic circuitry might be needed for amplification of impedance matching
- One group of such sensors is based on resonant structures (piezoelectric quartz resonators, SAW (surface acoustic wave) dual-line oscillators, etc.), another group is based on the periodic geometrical structure of the sensors (angle encoders)

**Examples:** inductive, photo impulse, string, acoustic and scintillation sensors

# $x(t) \rightarrow V(t) \rightarrow F(t)$ Conversion

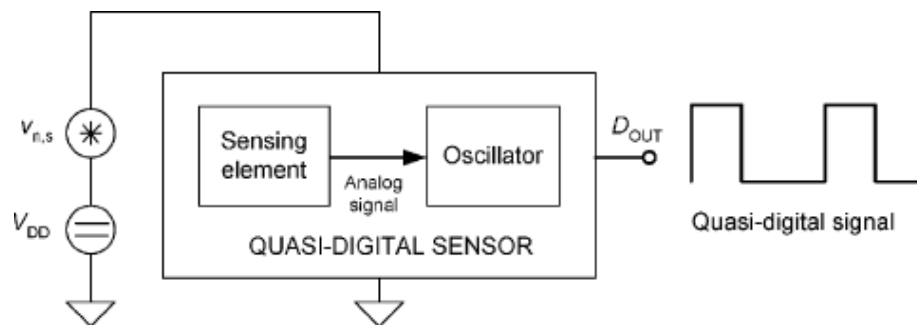

- It is rather numerous sensors group
- Simple voltage-to-frequency or current-to-frequency conversion circuit can be used

**Examples:** Hall sensors, thermocouple sensors and photo sensors based on valve photoelectric cells

# $x(t) \rightarrow V(t) \rightarrow P(t)$ Conversion

- Sensors of this group (electronic-oscillator based sensors) are rather manifold and numerous
- Sensor element itself is the frequency determining element

**Examples:** inductive, capacity and ohmic parametric (modulating) sensors

# Quasi-Digital Sensors Advantages

- High Noise Immunity
- High Power Signal
- Wide Dynamic Range
- High Accuracy of Reference
- Simple Interfacing
- Simple Integration and Coding
- Multiparametricity
- Self-Adaptability

# High Noise Immunity

- Objective property due to a frequency modulation
- Frequency signal can be transmitted by communication lines to much greater distance
- Only two-wire line is necessary for transmission of such signal
- Data transmitting does not require any synchronization
- Frequency signal is ideal for high noise industrial environments

# High Noise Immunity (cont.)

# High Power Signal

- Section from a sensor output up to an amplifier input is the heaviest section in a measuring channel for signal transmitting from a power point of view
- Losses, originating on this section can not be filled any more by any signal processing
- Output powers of frequency sensors, as a rule, are considerably higher

# Wide Dynamic Range

- Dynamic range is not limited by supply voltage and noise
- Dynamic range of over 160 dB can be easily obtained

# High Accuracy of Reference

- Crystal oscillators can be made more stable, than the voltage reference:
  - non-compensated crystal oscillator has up to  $(1 \div 50) \cdot 10^{-6}$  error
  - temperature-compensated crystal oscillator has up to  $10^{-8} \div 10^{-10}$  error
- Minimum possible error for frequency measurements with the help of quantum frequency standard is  $10^{-14}$ , minimum possible quantization step for time interval is  $10^{-12}$  seconds

# Simplicity of Interfacing

VS.

- Parasitic electromotive force (emf), transient resistances and cross-feed of channels in analog multiplexer at the usage of analog sensors are reasons for errors
- Frequency modulated signal is not sensitive to all listed factors
- Multiplexers for frequency output sensors and transducers are very simple and do not introduce any errors

# Multiparametricity

- One sensor's output - two informative parameters: a frequency is proportional to the physical quantity X and duty-cycle at the same output is proportional to the physical quantity Y
- Today there are some examples
- It is the future of multiparametric, multifunctional and combo sensors

# Self- Adaptability

- Versatility between accuracy and speed (time of measurement or conversion time)
- Trade-off between accuracy and power consumption

# Integrated FDC

- USP-30 one-chip specialized microprocessor (1980)
- IC of ALU for time interval measurements (1989)
- K512PS11 - frequency-to-digital converter (1990)
- USIC - universal sensor interface chip (1996)

# FDC ICs Disadvantages

- All ICs except TDCs are based on conventional methods of measurement, hence, quantization error is dependent on measurand frequency  $f_x$ , many of ICs have redundant conversion time
- They cannot be used with all existing modern frequency-time domain sensors due to low accuracy or/and narrow frequency ranges
- They do not cover all frequency–time informative parameters of electric signals

# μC-based Realization's Disadvantages

**Neither**

**nor**

**C/C++**

- Low metrological performance due to classical methods for frequency measurements
- All advanced conversion methods are patented
- Firmware realization contains many time-dependent pieces of code and must be written in *Assembler*
- Additional program related errors can be easily introduced during the design
